(Received 10 March 2010; published 18 June 2010)

The prototypical Casimir effect arises when a scalar field is confined between parallel Dirichlet boundaries. We study corrections to this when the boundaries themselves have apertures and edges. We consider several geometries: a single plate with a slit in it, perpendicular plates separated by a gap, and two parallel plates, one of which has a long slit of large width, related to the case of one plate being semi-infinite. We develop a general formalism for studying such problems, based on the wave functional for the field in the gap between the plates. This formalism leads to a lower-dimensional theory defined on the open regions of the plates or boundaries. The Casimir energy is then given in terms of the determinant of the nonlocal differential operator which defines the lower-dimensional theory. We develop perturbative methods for computing these determinants. Our results are in good agreement with known results based on Monte Carlo simulations. The method is well suited to isolating the diffractive contributions to the Casimir energy.

I. INTRODUCTION

The Casimir effect, as originally conceived, refers to the electromagnetic field in the presence of two infinite parallel conducting plates. The plates modify the boundary conditions on the field in a way which leads to a finite calculable shift in the ground state energy. Since the original work of Casimir [1], similar effects have been studied in a variety of different geometries, and a number of different calculational techniques have been developed. For a recent review see [2].

In the present work, we only consider scalar fields for simplicity. Our goal is to understand what happens when the boundaries themselves have edges. For instance, consider an infinite conducting plate with a hole in it. How does the size and shape of the hole modify the ground state energy? From the point of view of wave mechanics, the new feature is that the field can undergo diffraction as it passes through the hole. So our work could be viewed as the study of diffractive corrections to Casimir energies.

An outline of this paper is as follows. We first develop a general formalism for studying edge effects, based on writing a lower-dimensional effective action for the field which lives in the hole. The total volume in which the field theory is defined is considered to be split into separate regions by boundaries, some of which have open regions to achieve the required geometry of surfaces. The lower-dimensional field theory is defined on the open regions of boundaries. This lower-dimensional action can be obtained by integrating out the scalar field in the bulk (Sec. II A). We use this to study a single plate with a hole in it, and show that the Casimir energy can be expressed as the determinant of the nonlocal differential operator which defines the lower-dimensional theory (Sec. II B). Our effective action can also be described in terms of the wave functional of the field, projected onto the hole, providing a Hamiltonian type of interpretation where the normal to the surface takes on the role of time (Sec. II C). In Sec. III we specialize to a single plate with a long slit in it. We develop perturbative methods for computing the determinants, based on separating the operator into what could be considered as direct and diffractive contributions; mathematically these correspond to the “pole” (quasilocal) and “cut” (nonlocal) contributions in an integral representation. In Sec. IV these results are used to obtain the Casimir energy associated with two perpendicular plates separated by a gap. In Sec. V we study two parallel plates separated by a gap, obtaining the diffractive contribution to the Casimir energy when one of the plates is semi-infinite. In both these cases, we compare the values obtained from our analytical calculation with the numerical calculations of the same available in the literature. The results from the two approaches are in good agreement. The appendixes collect some mathematical results: the behavior of a field near a single plate with an edge (Appendix A) and heat kernels for the Laplacian with periodic and Dirichlet boundary conditions (Appendix B).

It is important to note that diffraction around solid obstacles does occur in many of the special geometries for which exact or close-to-exact results have been found. For the enormous amount of literature on such cases, we shall refer back to the reviews, except to point out that the multiple scattering techniques developed by a number of different groups [2–5], and the world line techniques of Gies et al. [6] do incorporate diffraction around such solid objects. Nevertheless, the Casimir energy due to diffraction around edges of openings in boundaries has been calcu-
II. AN EFFECTIVE ACTION FOR EDGE EFFECTS

As a prototype for the sort of problem we will consider, take a free massless scalar field in \( d \) Euclidean dimensions. Imagine it propagates in two regions (“left” and “right”) separated by a plate with a hole in it. Aside from the hole, we require that the field vanish everywhere on the boundary, while in the hole, we denote the fluctuating value of the field by \( \phi_0 \). This is illustrated in Fig. 1.

The basic idea is to write an effective action \( S_0 \) for the fluctuations of \( \phi_0 \). This effective action can be obtained in two different ways. From a path integral point of view it is a lower-dimensional effective action which arises from integrating out the scalar field in the bulk. From a Hamiltonian point of view, \( S_0 \) is related to the wave functional of \( \phi_0 \). This effective action can be obtained in two different ways. From a path integral point of view it is a lower-dimensional effective action which arises from integrating out the scalar field in the bulk. From a Hamiltonian point of view, \( S_0 \) is related to the wave functional of \( \phi_0 \).

A. Path integral approach

We start with the Euclidean partition function

\[
Z = \int \mathcal{D}\phi e^{-\int d^d x (1/2) \partial^2 \phi}.
\]

(1)

We fix the value of the field in the hole, \( \phi_{\text{hole}} = \phi_0 \), and subsequently integrate over \( \phi_0 \).

\[
Z = \int \mathcal{D}\phi_0 \int \mathcal{D}\phi e^{-\int d^d x (1/2) \partial^2 \phi}.
\]

(2)

To perform the bulk path integral we set

\[
\phi = \phi_{cl} + \delta \phi.
\]

(3)

Here \( \phi_{cl} \) is a solution to the classical equations of motion \( \Box \phi_{cl} = 0 \), subject to the boundary conditions

\[
\phi_{cl} = \begin{cases} 
\phi_0 & \text{in hole,} \\
0 & \text{elsewhere on boundary.}
\end{cases}
\]

(4)

FIG. 1. The field propagates in two regions separated by a plate with a hole. At the location of the hole, indicated by the dotted line, we denote the fluctuating value of the field by \( \phi_0 \). Elsewhere on the boundary, indicated by solid lines, we impose \( \phi = 0 \).

B. Hamiltonian approach

Integrating by parts, the classical action in (5) is a surface

\[
\int \partial_0 (\partial_0 + M) \phi_{cl}.
\]

(6)

where \( \partial_0 \) is a solution to the classical equations of motion \( \Box \phi = 0 \), subject to the boundary conditions

\[
\phi_{cl} = \begin{cases} 
\phi_0 & \text{in hole,} \\
0 & \text{elsewhere on boundary.}
\end{cases}
\]

(7)

appropriately for the left and the right sides.

The bulk determinants in (7) capture the Casimir energy that would be present if there were no hole. Corrections to this are given by a peculiar nonlocal field theory that lives on the hole separating the two regions; the fields \( \phi_0 \) are nonzero only on the hole. We can write a mode expansion for the fields \( \phi_0 \) as \( \phi_0(x) = \sum_a c_a u_a(x) \) where \( \{u_a(x)\} \) constitute a complete set of modes for functions which are nonzero in the hole with the boundary condition that \( u_a(x) \to 0 \) as one approaches the edges of the hole. The action (8) takes the form

\[
S_L = \frac{1}{2} \sum_{a, \beta} c_a O_{\alpha \beta} c_\beta,
\]

(11)

where
with similar expressions for the right side of the partition. Because the mode functions \( n_a(x) \) vanish outside the hole, this is essentially a projection of the operator \( M(x|x') \) to the hole. In other words, if we define an operator \( P \) which acts on functions \( f \in L^2(\mathbb{R}^{d-1}) \) by

\[
P f(x) = \begin{cases} f(x) & \text{if } x \in \text{hole}, \\ 0 & \text{otherwise}, \end{cases}
\]

then \( O = P M P \). The functional integration now leads to

\[
Z = \det^{-1/2}(-\Box_L)\det^{-1/2}(-\Box_R)\det^{-1/2}(O_L + O_R).
\]

The explicit form of the operator \( M(x|x') \), and its projected version \( O \), will, in general, depend on the arrangement of plates and holes and boundaries. We can clarify the nature of this operator by constructing the Green’s function with Dirichlet boundary conditions. For this, consider the right side of the box shown in Fig. 1. We split the coordinates \( x = (x,y) \) into \( d-1 \) coordinates \( x \) along the plate and a single transverse coordinate \( y \). The plate is taken to be at \( y = 0 \). (Thus \( y \) is along the horizontal axis in the figure.) The right side of the box has length \( a \) along the \( y \) direction, while we have lengths \( L_1, L_3, \) etc., along the other directions. The modes along the \( y \) direction are

\[
\psi_n(y) = \sqrt{\frac{2}{a}} \sin\left(\frac{n\pi y}{a}\right)
\]

for \( n = 1, 2, \text{etc.} \) Similarly, modes for the other directions take the form

\[
\psi_m(x_i) = \sqrt{\frac{2}{L_i}} \sin\left(\frac{m_i\pi x_i}{L_i}\right)
\]

with \( m_i = 1, 2, \text{etc.} \) The Green’s function for the left side can then be written as

\[
G(x|x') = -\sum_p \psi_m(x) \psi^*_m(x') \frac{1}{2} \sum_n \frac{1}{a^2n} \cdot \frac{1}{p + n^2\pi^2/a^2} \\
\times \sin\left(\frac{n\pi y}{a}\right) \sin\left(\frac{n\pi y'}{a}\right).
\]

The summation over \( n \) can be carried out by complex integration (or other methods) to obtain

\[
G(x|x') = -\sum_p \frac{1}{2} \psi_m(x) \psi^*_m(x') \coth(ap) \\
\times [\cosh p(y - y') - \cosh p(y + y')].
\]

where \( p = \sqrt{p \cdot p} \). This immediately leads to

\[
O_{L\alpha\beta} = \int_{\text{hole}} d^{d-1}x d^{d-1}x' u_{\alpha}(x) M_L(x|x')u_{\beta}(x')
\]

where \( b \) is the length (along \( y \)) of the left side of the box. For the parallel plate geometry, we are interested in the limit when \( b \to \infty \) and \( L_1 \to \infty \). The other cases we shall consider in this paper will also be special cases of the Eqs. (19) and (20).

### B. Single plate with a hole

We can now go on to the projected version \( O \) of the operator \( M(x|x') \). For this, we will first consider the example of a single plate with a hole in it. In this case, we are interested in \( a \to \infty \) and \( b \to \infty \). Further, since \( L_1 \to \infty \), we can approximate the sum over \( p \) by integration, to obtain

\[
M(x|x') = \int \frac{d^{d-1}p}{(2\pi)^{d-1}} e^{ip \cdot (x - x')} \sqrt{p \cdot p}.
\]

This result may also be obtained in a simpler way, without the full mode expansion, by noting that the standard Euclidean Green’s function is

\[
G(x, y|x', y') = \frac{1}{(d - 2)\text{vol}(S^{d-1})} \frac{1}{\|x - x'|^2 + (y - y')^2}.
\]

The Green’s function appropriate to the plate geometry (Dirichlet boundary conditions at \( y = 0 \)) can be constructed with the help of an image charge,

\[
G_D(x, y|x', y') = G(x, y|x', y') - G(x, y|x', -y').
\]

The quantity we need is

\[
\partial_x \partial_y G_D |_{y \to y'} - \frac{2}{\text{vol}(S^{d-1})} \frac{1}{\|x - x'|^2 + (y - y')^2(y^2 + y'^2)^{d/2}}.
\]

where we have kept \( y \to 0^+ \) as a regulator. This is a quite singular-looking distribution: for \( x \neq x' \) it approaches \( 1/\|x - x'|^d \), while at \( x = x' \) it diverges as \( -1/y^d \).

To interpret this expression we return to the bulk equations of motion \((\nabla^2_k + \partial_y^2) \phi = 0\). A complete set of solutions is

\[
\phi_{\text{cl}}(x, y) = e^{ik \cdot x} e^{-ky} \text{ for } y > 0.
\]

Notice that \( n \cdot \partial \phi_{\text{cl}} = -\partial_y \phi_{\text{cl}} = k \phi_{\text{cl}} \), so that we can identify

\[
n \cdot \partial \phi_{\text{cl}}|_{y \to 0} = \sqrt{-\nabla_k^2} \phi_{\text{cl}}|_{y \to 0}.
\]
Denoting the value of the field at $y = 0$ by $\phi_0$, and acting on (6) with $n \cdot \partial|_{y=0}$, this implies that

$$
\int d^{d-1}x' \phi_0(x') \partial_y \phi_0 = \sqrt{-\nabla^2} \phi_0(x), \quad (23)
$$

In other words, the distribution (22) is the square root of the Laplacian. Then the actions (8) and (9) are

$$
S_L = S_R = \int d^{d-1}x \frac{1}{2} \phi_0 \sqrt{-\nabla^2} \phi_0 \quad (24)
$$

and the partition function (7) is

$$
Z = \text{det}^{-1/2}(\square_L) \text{det}^{-1/2}(\square_R) \times \int \mathcal{D}\phi_0 \exp \left\{ -\int d^{d-1}x \phi_0 \sqrt{-\nabla^2} \phi_0 \right\} \quad (25)
$$

In this expression $\sqrt{-\nabla^2}$ refers to the square root of the Laplacian on $\mathbb{R}^{d-1}$, since that is what the arguments leading to (23) really establish. But the path integral in (25) is over fields which vanish outside the hole. Denoting this qualification by the projection operator, the path integral can be evaluated to give

$$
Z = \text{det}^{-1/2}(\square_L) \text{det}^{-1/2}(\square_R) \text{det}^{-1/2}(P \sqrt{-\nabla^2} P). \quad (26)
$$

The two bulk determinants can be absorbed by renormalizing the bulk cosmological constant and the plate tension, so the dependence on the size and shape of the hole is captured by

$$
Z = \text{det}^{-1/2}(P \sqrt{-\nabla^2} P). \quad (26)
$$

C. Hamiltonian interpretation

For an infinite plate with a hole our expression for the Casimir energy has a simple Hamiltonian interpretation. Let us regard $y$ as a Euclidean time coordinate. In an unbounded space the vacuum wave functional for the field is given by a Euclidean path integral over the region $y > 0$.

$$
\Psi_0[\phi_0] = \int_{\phi(x,y=0) = \phi_0(x)} \mathcal{D}\phi e^{-\int d^{d-1}x \int_0^{\infty} dy (1/2) \phi \cdot \partial_y \phi}. \quad (27)
$$

Note that $\phi_0$ is defined over the entire $x$ plane. Following the logic in Sec. II A, this means the vacuum wave functional is

$$
\Psi_0[\phi_0] = \text{det}^{-1/2}(\square_L) e^{-S_L[\phi_0]},
$$

which, given (24), can be put in the familiar form [9,10]

$$
\Psi_0[\phi_0] = \text{det}^{-1/2}(\square_L) e^{-\int d^{d-1}x (1/2) \phi_0 \sqrt{-\nabla^2} \phi_0}. \quad (28)
$$

So our expression (7) for the partition function is really

$$
Z = \int_{\phi_0 \text{ outside hole}} \mathcal{D}\phi_0 \Psi_0[\phi_0] \Psi_0[\phi_0].
$$

That is, to obtain the partition function we

1. Start with the vacuum state in the far past, at $y = -\infty$.
2. Evolve forward in time to $y = 0$.
3. Impose a Dirichlet condition by only considering fields which vanish in the region outside the hole.
4. Take the overlap with the vacuum state in the far future, evolved backward in time to $y = 0$.

For a single plate with a hole our effective action is related to the vacuum wave functional by

$$
e^{-S[\phi_0]} = \Psi_0[\phi_0] \Psi_0[\phi_0].
$$

A similar result holds in general, although with more complicated plate geometries one no longer has the standard vacuum wave functionals on the left and right.

III. PLATE WITH A SLIT

For a single plate with a hole we have obtained a simple expression for the partition function,

$$
Z = \text{det}^{-1/2}(P \sqrt{-\nabla^2} P),
$$

where $P$ is a projection operator onto the hole and $\sqrt{-\nabla^2}$ is the square root of the Laplacian on $\mathbb{R}^{d-1}$. To make further progress we now specialize to the case where the hole is a long slit of width $2a$. The geometry is shown in Fig. 2. We first work in two dimensions, with a scalar field of mass $\mu$. For a slit in higher dimensions, $\mu$ arises from Kaluza-Klein momentum along the transverse directions, so we can subsequently integrate over $\mu$ to obtain results appropriate to the dimension.

In two dimensions the projection operator is

$$
Pf(x) = \begin{cases} f(x) & -a < x < a, \\ 0 & \text{otherwise,} \end{cases} \quad (29)
$$

while $\sqrt{-\nabla^2}$ can be defined by its spectral representation

$$
\sqrt{-\nabla^2} e^{ikx} = |k| e^{ikx} \quad k \in \mathbb{R}.
$$

However the operator we need to study is

$$
\mathcal{O} = P \sqrt{-\nabla^2} + \mu^2 P.
$$

This is not an easy operator to work with. In Appendix A

$$
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
ax \quad x = a
\end{array}
\end{array}
\end{array}
$$

FIG. 2. In two Euclidean dimensions the slit geometry consists of two whiskers facing each other, separated by a distance $2a$. 

---

1We are grateful to Alexios Polychronakos for discussions on this point.

2The stress tensor associated with an infinite Dirichlet plate is discussed by Birrell and Davies [8], Sec. 4.3.
we diagonalize it for a slit of infinite width. But for a slit of finite width we must resort to some sort of approximation scheme.

To do this we note that by construction the field vanishes for \( x \geq a \) and \( x \leq -a \). Moreover \( \mathcal{O} \) respects a parity symmetry \( x \rightarrow -x \). We therefore expect that we can expand the field in a complete set of odd- and even-parity functions which vanish for \( |x| \geq a \), namely

\[
\psi_m^{\text{odd}} = \begin{cases} 
(-1)^m \frac{1}{\sqrt{a}} \sin(m \pi x/a) & \text{for } -a \leq x \leq a, \\
0 & \text{otherwise},
\end{cases}
\]

\[
(28)
\]

\[
\psi_p^{\text{even}} = \begin{cases} 
(-1)^{p+(1/2)} \frac{1}{\sqrt{a}} \cos(p \pi x/a) & \text{for } -a \leq x \leq a, \\
0 & \text{otherwise}.
\end{cases}
\]

The odd modes are labeled by \( n, m = 1, 2, 3, \ldots \), while the even modes carry an index \( p, q = \frac{1}{2}, \frac{1}{2}, \ldots \). These modes are orthonormal; the factors of \((-1)^m\) and \((-1)^{p+(1/2)}\) are inserted for later convenience.

These modes are eigenfunctions of the Laplacian with Dirichlet boundary conditions at \( x = a \) and \( x = -a \). We will use them as a basis in which to diagonalize \( \mathcal{O} = \mathcal{P} \sqrt{-\nabla^2 + \mu^2} \mathcal{P} \). In this basis it turns out that \( \mathcal{O} \) naturally splits into two pieces: a pole piece which is quasilocal and can be diagonalized, and a cut piece which is truly nonlocal.

As a guide for the reader, in Sec. III A we consider the decomposition of \( \mathcal{O} \) into its pole and cut contributions. In Sec. III B we set up the perturbation series and derive integral expressions for all higher terms in this expansion of the partition function. In Sec. III C we integrate over the mass to find the ground state energy for a plate with a slit in four dimensions.

### A. Pole and cut contributions

We begin by considering the odd-parity modes (28). They have a Fourier sine representation

\[
\psi_n^{\text{odd}} = \frac{2 \sqrt{a}}{\pi} \int_0^\infty dk \frac{n \pi}{k^2 a^2 - n^2 \pi^2} \sin(ka) \sin(kx).
\]

Clearly \( P \psi_n^{\text{odd}} = \psi_n^{\text{odd}} \), while for any function of the Laplacian we have

\[
F(-\nabla^2)\psi_n^{\text{odd}} = \frac{2 \sqrt{a}}{\pi} \int_0^\infty dk \frac{n \pi F(k^2)}{k^2 a^2 - n^2 \pi^2} \sin(ka) \sin(kx).
\]

It follows that the matrix elements in this basis are

\[
\mathcal{O}_{mn}^{\text{odd}} = \langle m|P\sqrt{-\nabla^2 + \mu^2}P|n \rangle
\]

\[
= \frac{2a}{\pi} \int_{-\infty}^{\infty} dk \sin^2(ka) \frac{m \pi}{k^2 a^2 - n^2 \pi^2}
\]

\[
\times \sqrt{k^2 + \mu^2} \frac{n \pi}{k^2 a^2 - n^2 \pi^2}.
\]

Despite appearances, there are no singularities on the contour of integration: the would-be poles at \( k = \pm m \pi/a \) and \( \pm n \pi/a \) cancel against the zeroes of \( \sin(ka) \).

Although \( \mathcal{O} \) is not diagonal in this basis, the diagonal matrix elements are numerically much larger than the off-diagonal elements. There is a way of decomposing \( \mathcal{O} \) which makes this manifest. First deform the integration contour slightly, moving it just above the real \( k \) axis (see Fig. 3). Then write

\[
\sin^2(ka) = -\frac{1}{4}(e^{2ika} + e^{-2ika} - 2).
\]

For each term in this decomposition the integration contour can be deformed into the upper or lower half-plane. One picks up a contribution if the integration contour crosses the poles (now real) at \( k = \pm m \pi/a \) or \( \pm n \pi/a \). One also gets a contribution when the contours get wrapped around the cuts. The residues turn out to cancel unless \( m = n \), so the pole contribution to the matrix element is diagonal. In fact

\[
\mathcal{O}_{mn}^{\text{odd,pole}} = \frac{1}{a} \frac{n \pi}{n^2 \pi^2 + \mu^2 a^2} \delta_{mn}.
\]

The cut contribution to the matrix element is not diagonal. Rather we find

\[
\mathcal{O}_{mn}^{\text{cut}} = \frac{2a}{\pi} \int_{-\infty}^{\infty} dk \sin^2(ka) \frac{m \pi}{k^2 a^2 - n^2 \pi^2}
\]

\[
\times \sqrt{k^2 + \mu^2} \frac{n \pi}{k^2 a^2 - n^2 \pi^2}.
\]

![FIG. 3. The contour for integrating over \( k \).](image-url)

---

\(^3\)Meaning a single plate with an edge, described by

\[
Pf(x) = \begin{cases} 
f(x) & x > 0, \\
0 & x < 0.
\end{cases}
\]

\(^4\)One might question whether these modes provide a good basis in which to diagonalize \( \mathcal{O} \). This seems justified by the results of Appendix A, where we show that the exact eigenfunctions of \( \mathcal{O} \) indeed go to zero as one approaches the edge of the slit (in fact they vanish as the square root of the distance from the edge).
\[ \mathcal{O}^{\text{odd, cut}}_{pq} = - \frac{2\mu^2 a}{\pi} \left( \frac{2}{\int_1^\infty dy \sqrt{y^2 - 1(1 - e^{-2\mu ay})}} \right) \times \frac{m \pi}{m^2 \pi^2 + \mu^2 a^2 \gamma^2 - n^2 \pi^2 + \mu^2 a^2 \gamma^2}. \]  

(31)

Here \( y = \text{Im} k/\mu \) is an integration variable along the cut.

Likewise the even-parity modes (29) have a Fourier cosine representation

\[ \psi_{\text{even}}^p = \frac{2\sqrt{a}}{\pi} \int_0^\infty dk \frac{p \pi}{k^2 - p^2 \pi^2} \cos(ka) \cos(kx) \]

and the matrix elements of \( \mathcal{O} \) in the even-parity sector are

\[ \mathcal{O}^{\text{even}}_{pq} = \frac{2a}{\pi} \int_{-\infty}^\infty dk \cos^2(ka) \frac{p \pi}{k^2 + \mu^2 a^2 - p^2 \pi^2} \times \sqrt{k^2 + \mu^2 a^2 - q^2 \pi^2}. \]

Deforming contours as before leads to the decomposition

\[ \mathcal{O}_{pq} = \mathcal{O}_{pq}^{\text{pole}} + \mathcal{O}_{pq}^{\text{cut}}, \]

where

\[ \mathcal{O}_{pq}^{\text{even, pole}} = \frac{1}{a} \sqrt{p^2 \pi^2 + \mu^2 a^2} \delta_{pq}, \]

\[ \mathcal{O}_{pq}^{\text{even, cut}} = - \frac{2\mu^2 a}{\pi} \int_1^\infty dy \sqrt{y^2 - 1(1 + e^{-2\mu ay})} \]

\[ \times \frac{p \pi}{q \pi} \frac{q \pi}{p^2 \pi^2 + \mu^2 a^2 \gamma^2 - q^2 \pi^2 + \mu^2 a^2 \gamma^2}. \]

(32)

Note the opposite sign in front of the exponential, due to the fact that the even-parity matrix elements involved \( \cos^2 ka \) rather than \( \sin^2 ka \).

Combining the even- and odd-parity matrix elements, note that \( \mathcal{O}^{\text{pole}} \) can be identified with the operator \( \sqrt{-\nabla_D^2 + \mu^2} \), where \( \nabla_D^2 \) denotes the Laplacian with Dirichlet boundary conditions at \( x = \pm a \). So although \( \mathcal{O}^{\text{pole}} \) is not a local differential operator, its square is local, and in this sense we will refer to \( \mathcal{O}^{\text{pole}} \) as being quasilocal.

The cut contributions, on the other hand, make a truly nonlocal contribution to the operator \( \mathcal{O} \).

From the physical point of view the decomposition into pole and cut contributions is natural because \( \mathcal{O}^{\text{pole}} \) captures the geometrical optics effects of the hole, in which waves are directly transmitted from left to right, while \( \mathcal{O}^{\text{cut}} \) captures the diffractive effects. This follows from the observation made above, that \( \mathcal{O}^{\text{pole}} \) is related to an operator with Dirichlet boundary conditions at the edges of the hole. Such boundary conditions could be enforced by introducing additional plates as shown in Fig. 4. The additional plates prevent any diffraction from taking place, so diffractive effects are entirely encoded in \( \mathcal{O}^{\text{cut}} \).

\[ \mathcal{O} = \mathcal{O}^{\text{pole}} + \mathcal{O}^{\text{cut}} \]

B. Perturbation expansion

Having decomposed the operator \( \mathcal{O} = \mathcal{O}^{\text{pole}} + \mathcal{O}^{\text{cut}} \) into direct and diffractive contributions, we wish to find a similar decomposition of the Casimir energy. This is straightforward. Expanding in powers of \( \mathcal{O}^{\text{cut}} \), the partition function is

\[ - \log Z = \frac{1}{2} \text{Tr} \log (\mathcal{O}^{\text{pole}} + \mathcal{O}^{\text{cut}}) \]

\[ = \frac{1}{2} \text{Tr} \log \mathcal{O}^{\text{pole}} + \frac{1}{2} \text{Tr} \mathcal{O}^{-1} \mathcal{O}^{\text{cut}} \]

\[ - \frac{1}{4} \text{Tr} \mathcal{O}^{-1} \mathcal{O}_{\text{cut}} \mathcal{O}^{-1} \mathcal{O}_{\text{cut}} + \cdots. \]

(33)

The zeroth order term in this expansion gives the direct contribution to the energy, while the first and higher order terms give the diffractive contribution.

Writing things in this way, the diffractive contribution to the energy is organized as a series expansion in powers of \( \mathcal{O}^{\text{cut}} \). This expansion seems to be well behaved, even though there is no small parameter in the problem.\(^5\) We give a speculative reason for this in the conclusions. But more prosaically the good behavior of the perturbation series will become evident from the explicit calculations we perform in the remainder of this paper, where we work up to 5th order in \( \mathcal{O}^{\text{cut}} \). For a graphical preview of the results see Fig. 5.

The lowest-order term in the perturbation series (33), the direct term, has a linear divergence and a subdominant logarithmic divergence, while all higher order terms, corresponding to diffractive contributions, are logarithmically divergent. These logarithmic divergences are independent of \( a \) and can be eliminated by subtracting the \( a \to \infty \) limit. This can be done either from the beginning, before the expansion in powers of \( \mathcal{O}^{\text{cut}} \), or at the level of each term in the expansion.

These subtractions can be interpreted as renormalizations of parameters corresponding to the plates and slits. Strictly speaking, in addition to the action for the fields, we

\[ \text{FIG. 4.} \]

On the left, the geometry of interest. On the right, the geometry described by \( \mathcal{O}^{\text{pole}} \), in which additional plates have been added to enforce Dirichlet boundary conditions at the edges of the hole.

\(^5\)Note that the diffractive contribution to the energy does not in general have to be small compared to the direct contribution. Rather what we are claiming is that the diffractive contribution by itself has a useful series expansion in powers of \( \mathcal{O}^{\text{cut}} \).
have an action which describes the plates and slits in the given arrangement. This part of the action is generally of the form

$$S = \sigma \mathcal{A} + \alpha \mathcal{L} + \cdots,$$

where $\mathcal{A}$ is the area of the plate, and $\mathcal{L}$ is the length of the perimeters involved (for the plate and for any slits or holes in it). The coefficients $\sigma$ and $\alpha$ are the tensions for the plate and the edges of the slits. Being the coefficients of the area and perimeter terms, in the language of general relativity, they are the cosmological constants for the plate and for the boundaries. While these are calculable in terms of the material properties of the plates, at the level we are working, with the effects of the plates introduced as merely boundary conditions, they are free parameters. The partition function and the free energy we calculate are to be thought of as giving corrections to this action (34). The divergent terms we find can be absorbed as renormalization, independent of $\alpha$, which renormalizes the cosmological constant (i.e. the tension associated with the edges of the slit). After these divergences are removed one is left with a finite result which vanishes exponentially as $a \to \infty$. In the notation of Appendix B,

$$- \log Z^{(0)}_{\text{renormalized}} = - \frac{1}{4} \int_0^\infty ds \frac{ds}{s} e^{-s \mu^2}$$

$$\times \left( K_D(s, 2a) - \frac{a}{\sqrt{\pi s}} + \frac{1}{2} \right)$$

$$= - \frac{a}{2 \sqrt{\pi}} \int_0^\infty ds \frac{s^{1/2}}{s^{1/2}} e^{-s \mu^2} \sum_{n=1}^\infty e^{-4n^2a^2/s}$$

$$= \frac{1}{4} \log(1 - e^{-4\mu a}).$$

2. The diffractive contributions

For the first order term it is useful to separate the contributions from the odd- and even-parity terms as

$$- \log Z^{(1)} = - \log Z^{(1)}_{\text{odd}} - \log Z^{(1)}_{\text{even}},$$

where

$$- \log Z^{(1)}_{\text{odd}} = - \frac{(\mu a)^2}{\pi} \int_1^\infty dy \sqrt{y^2 - 1} \sum_{r=1,2,\ldots} (1 - e^{-2\mu a y}) \frac{y^2 \pi^2}{\sqrt{r^2 \pi^2 + \mu^2 a^2(r^2 \pi^2 + \mu^2 a^2 y^2)^2}},$$

$$- \log Z^{(1)}_{\text{even}} = - \frac{(\mu a)^2}{\pi} \int_1^\infty dy \sqrt{y^2 - 1} \sum_{r=1/2,1,\ldots} (1 + e^{-2\mu a y}) \frac{y^2 \pi^2}{\sqrt{r^2 \pi^2 + \mu^2 a^2(r^2 \pi^2 + \mu^2 a^2 y^2)^2}}.$$
Again, by use of partial fractions and (41), we can write this as

\[ T(\mu a, y, z) = \frac{\mu^2 a^2}{\pi} \sum_{r=1,2,z} \frac{r^2 \pi^2}{\sqrt{r^2 \pi^2 + \mu^2 a^2 (r^2 \pi^2 + \mu^2 a^2 y^2)(r^2 \pi^2 + \mu^2 a^2 z^2)}. \]

By resolving the integrand into partial fractions, the summation can be done using

\[ \sum_{r} \frac{1}{r^2 \pi^2 + A^2} = \frac{1}{2A^2} \ln[A \coth A - 1]. \]

We can then write \( T \) as

\[ T(\mu a, y, z) = \frac{1}{\pi} \int_0^\infty d\lambda \left[ -\frac{\sqrt{\lambda^2 + 1} \coth(\mu a \sqrt{\lambda^2 + 1})}{(\lambda^2 + 1 - y^2)(\lambda^2 + 1 - z^2)} + \frac{y \coth(\mu a y)}{(y^2 - z^2)(\lambda^2 + 1 - y^2)} + \frac{z \coth(\mu a z)}{(z^2 - y^2)(\lambda^2 + 1 - z^2)} \right]. \]

The limit of \( z \to y \) is seen to be

\[ T(\mu a, y, y) = \frac{1}{2\pi^2 y} \int_0^\infty dy \int_0^\infty d\lambda \left[ -\frac{\sqrt{\lambda^2 + 1} \coth(\mu a \sqrt{\lambda^2 + 1}) + y \coth(\mu a y)}{\lambda^2 + 1 - y^2} \right]. \]

The \( a \to \infty \) limit of these expressions is logarithmically divergent. The renormalized contribution is obtained after subtraction of this divergence as

\[ -\log Z_{\text{odd,ren}}^{(1)} = -\int_1^\infty dy \sqrt{y^2 - 1} \left[ (1 - e^{-2\mu a y}) T(\mu a, y, y) - T(\mu a \to \infty, y, y) \right]. \]

Similarly, for the even-parity contribution, we define

\[ S(\mu a, y, z) = \frac{\mu^2 a^2}{\pi} \sum_{r=1,2,z} \frac{r^2 \pi^2}{\sqrt{r^2 \pi^2 + \mu^2 a^2 (r^2 \pi^2 + \mu^2 a^2 y^2)(r^2 \pi^2 + \mu^2 a^2 z^2)}. \]

Again, by use of partial fractions and (41), we can write this as

\[ S(\mu a, y, z) = \frac{1}{\pi} \int_0^\infty d\lambda \left[ -\frac{\sqrt{\lambda^2 + 1}[\coth(2\mu a \sqrt{\lambda^2 + 1}) - \csch(2\mu a \sqrt{\lambda^2 + 1})]}{(\lambda^2 + 1 - y^2)(\lambda^2 + 1 - z^2)} + \frac{y[\coth(2\mu a y) - \csch(2\mu a y)]}{(y^2 - z^2)(\lambda^2 + 1 - y^2)} \right]. \]

The renormalized expression for the even-parity contribution is then

\[ -\log Z_{\text{even,ren}}^{(1)} = -\int_1^\infty dy \sqrt{y^2 - 1} \left[ (1 + e^{-2\mu a y}) S(\mu a, y, y) - S(\mu a \to \infty, y, y) \right]. \]

The higher order terms can also be written down easily in terms of \( T(\mu a, y, z) \) and \( S(\mu a, y, z) \) as

\[ -\log Z_{\text{odd}}^{(n)} = -\frac{2n-1}{n} \int_1^\infty \prod_i^n dy_i \sqrt{y_i^2 - 1} \left[ \prod_i^n (1 - e^{-2\mu a y_i}) T(\mu a) * T(\mu a) * \cdots * T(\mu a) - (\mu a \to \infty) \right]. \]
with a similar expression for the $S$'s.

The integrals involved in these formulas can be computed numerically as a function of $\mu a$. The direct term and the first two diffractive contributions are shown in Fig. 5. Notice that the second order diffractive term is much smaller than the first order term, consistent with our expectation of the usefulness of the expansion (33).

C. Slits in 4 dimensions

We can now extend our results to the physical setting of four dimensions by introducing two more dimensions: a periodic Euclidean time dimension of size $\beta$ (representing the inverse temperature), and a space dimension of size $L$ (representing the length measured along the edge of the slit). For large $\beta$ and $L$ the 4-dimensional partition function is an integral,

$$-\log Z_{4d} = \beta L \int \frac{d^2 \mu}{(2\pi)^2} (-\log Z_{2d}).$$  \hspace{1cm} (52)

where we are interpreting the momentum in the extra dimensions as providing a Kaluza-Klein mass. This means the energy per unit length for a slit in four dimensions is

$$E = \int_0^\infty \frac{\mu d\mu}{2\pi} (-\log Z_{2d}).$$  \hspace{1cm} (53)

The direct contribution is thus given, using (36), by

$$E^{(0)} = -\frac{\zeta(3) L}{128 \pi a^2} = \frac{L}{a^2} (-2.99 \times 10^{-3}).$$  \hspace{1cm} (54)

The diffractive contributions, obtained by integrating $-\log Z^{(n)}$ from (44) and (48)-(50), are

$$E^{(1)} = \frac{L}{a^2} (2.15 \times 10^{-3}), \quad E^{(2)} = \frac{L}{a^2} (0.14 \times 10^{-3}).$$  \hspace{1cm} (55)

The total value of the energy, to this order, is $-0.70 \times 10^{-3} (L/a^2)$. The $1/a^2$ dependence of these results is, of course, fixed by dimensional analysis.

We may also note that the energy for a slit in arbitrary number of dimensions can be obtained by extending the integration over $\mu$ in (52) to higher dimensions.

IV. PERPENDICULAR PLATES

In this section we study the ground state energy for two perpendicular plates separated by a distance $a$. The geometry is shown in the left panel of Fig. 6. Again our basic approach is to write a lower-dimensional effective action in the gap between the plates, indicated by the dotted line in the figure. Fortunately this turns out to require very little effort. The odd-parity modes in a slit that we studied in Sec. III vanish at $x = 0$. Thus they are appropriate for the case of there being a plate perpendicular to the slit as in the right panel of Fig. 6. We are interested basically in one side of this geometry. Notice however that the modes relevant for this case, namely, for $0 \leq x \leq a$ are in one-to-one correspondence with the modes relevant for the slit $-a \leq x \leq a$. The eigenvalues are also the same. The determinant is then given by the result for the odd-parity modes of the slit. So to obtain the Casimir of the two perpendicular plates, we can take the result for $-\log Z_{2d}$ discussed in the previous section, but restricted to the odd-parity modes, and then integrate over $\mu$ for the appropriate number of transverse dimensions.$^7$

Carrying out the integrations in four dimensions, we find

$$E^{(0)}_\perp = \frac{L}{a^2} (-11.96 \times 10^{-3}), \quad E^{(1)}_\perp = \frac{L}{a^2} (5.01 \times 10^{-3}),$$

$$E^{(2)}_\perp = \frac{L}{a^2} (0.66 \times 10^{-3}), \quad E^{(3)}_\perp = \frac{L}{a^2} (0.16 \times 10^{-3}),$$

$$E^{(4)}_\perp = \frac{L}{a^2} (0.05 \times 10^{-3}), \quad E^{(5)}_\perp = \frac{L}{a^2} (0.01 \times 10^{-3}).$$  \hspace{1cm} (56)

The total value for the $E_\perp$ up to this order is $-6.07(2) \times 10^{-3} (L/a^2)$. The terms in (56) have been evaluated using MATHEMATICA. The $n$th order term involves $2n + 1$ integrals. As the number of integrals increases, the precision of the answers is lowered. We used several integration methods for multidimensional integrals. Comparing results from different integration methods we estimate the error in our final answer for the total value to be within $0.02 \times 10^{-3}$.

The Casimir energy for two perpendicular plates separated by a gap has been numerically investigated by Gies and Klingmüller [7]. Their calculation is done by consid-

---

$^6$While we use periodic boundary condition for the time direction, we will retain Dirichlet conditions for the spatial directions. In the limit of large $L$, we can replace summations over momenta along this spatial dimension by integration. The distinction between Dirichlet conditions and periodic boundary conditions will not matter as $L \to \infty$.

$^7$The result for the full geometry of the right panel will require independent modes for the left and right sides of the vertical plate. We must use modes $\sin(n \pi x/a)\sin(m \pi y/a)$ with $m$, $n$ being independently chosen integers. This will lead to a doubling of our results for that geometry.
erating a path integral representation for the propagator. When the two plates are present, all paths which touch both plates must be considered as an overcounting of paths and must be removed from the sum over paths. This process, in a Monte Carlo evaluation of the path integral, then leads to corrections to the pure vacuum result and gives the Casimir energy. Their final result for two perpendicular plates is given as

$$E_\perp = \frac{L}{a^2}(-6.00(2) \times 10^{-3}).$$

Clearly our result is in very good agreement with the above value calculated in [7].

V. PARALLEL PLATES

Consider an infinite plate with a hole in it, parallel to a second infinite plate with no hole. Let the separation distance between the plates be $a$. The geometry is shown in Fig. 7.

It is straightforward to study this situation along the lines of Sec. II. We are interested in keeping $a$ finite but taking $b \to \infty$. In this case

$$M_L(x|x') + M_R(x|x') = \sum_p \psi_m(x) \psi_m(x') P(1 + \coth(a P)).$$

(58)

Since $\psi_m(x)$ form a complete set of states, this is basically the operator $\sqrt{-\nabla^2}(1 + \coth(\sqrt{-\nabla^2}))$. Once again, an alternative way to arrive at the above equation is the following. A complete set of solutions to the bulk equations of motion in the region between the plates is

$$\phi_{cl}(x, y) = e^{ikx}(Ae^{-ky} + Be^{ky}),$$

FIG. 7. Parallel plate geometry. The $z$ axis is into the page.

where the Dirichlet boundary conditions at $y = a$ fix

$$B = -Ae^{-2ka}.$$

Note that

$$n \cdot \partial \phi_{cl}|_{y=0} = -\partial_y \phi_{cl}|_{y=0} = k(A - B)e^{ikx}$$

$$= k \frac{A - B}{A + B} \phi_{cl}|_{y=0}.$$

This means that we can identify

$$n \cdot \partial \phi_{cl}|_{y=0} = \frac{\sqrt{-\nabla^2}}{\tanh(a\sqrt{-\nabla^2})} \phi_{cl}|_{y=0}.$$

The actions (8) and (9) are then given by

$$S_L = \int d^{d-1}x \frac{1}{2} \phi_0 \sqrt{-\nabla^2} \phi_0,$$

(59)

$$S_R = \int d^{d-1}x \frac{1}{2} \phi_0 \sqrt{-\nabla^2} \phi_0.$$

(60)

This can also be interpreted in the Hamiltonian language of Sec. II C. The wave functional on the left has the standard vacuum form

$$\Psi_L[\phi_0] = \det^{-1/2}(-\Box_L) \exp\left(-\int d^{d-1}x \frac{1}{2} \phi_0 \sqrt{-\nabla^2} \phi_0\right),$$

while the presence of the second plate modifies the wave functional on the right to

$$\Psi_R[\phi_0] = \det^{-1/2}(-\Box_R) \exp\left(-\int d^{d-1}x \frac{1}{2} \phi_0 \sqrt{-\nabla^2} \phi_0\right) \times \coth(\sqrt{-\nabla^2}) \phi_0,$$

From either perspective, the partition function (7) is

$$Z = \det^{-1/2}(-\Box_L) \det^{-1/2}(-\Box_R) \times \det^{-1/2}[P(\sqrt{-\nabla^2} + \sqrt{-\nabla^2} \coth(\sqrt{-\nabla^2})) P],$$

(61)

in agreement with (14) and (58). Just to be clear: the first determinant is computed in the region $y < 0$ with a Dirichlet boundary condition at $y = 0$. The second determinant is computed in the region $0 < y < a$ with Dirichlet boundary conditions at $y = 0$ and $y = a$. In the third determinant $P$ is a projection operator onto the hole and $\sqrt{-\nabla^2}$ is the Laplacian on $\mathbb{R}^{d-1}$.

The first determinant, $\det^{-1/2}(-\Box_L)$, can be renormalized away. The second determinant, $\det^{-1/2}(-\Box_R)$, gives the Casimir energy that two parallel plates would have if there were no hole. In $3 + 1$ dimensions this Casimir energy, per unit area, is given by the standard result

$$\frac{E}{A} = -\frac{\pi^2}{14400a^3}.$$

(62)
But in our case, for the sake of comparison with numerical results, it is important to specify boundary conditions at infinity (meaning on the walls of the box shown in Fig. 1).

In that figure, if we increase the size of the hole until it reaches the walls of the box, the condition that \( \phi \) vanishes at the edge of the hole is carried over to a Dirichlet condition on the walls of the box. So increasing the size of the hole is consistent provided we use Dirichlet boundary conditions at infinity. That is, \( \det^{-1/2}(\Delta_R) \) should be computed in a box of size \( L_1 \times a \times L_3 \), where \( L_1, L_3 \rightarrow \infty \) are the lengths in the \( x, z \) directions. This leads to subdominant terms in the Casimir energy, namely

\[
E = -\frac{\pi^2}{1440a^3} L_1 L_3 + \frac{\zeta(3)}{64 \pi a^2} (2L_1 + 2L_3) + \cdots. \tag{63}
\]

Other choices of boundary conditions at infinity are possible. For instance, if we use periodic boundary conditions in the \( z \) direction, the term \( \zeta(3) L_1 / 32 \pi a^2 \) is absent and we would have

\[
E = -\frac{\pi^2}{1440a^3} L_1 L_3 + \frac{\zeta(3)}{32 \pi a^2} L_3 + \cdots. \tag{64}
\]

For simplicity this is the case we will treat in the following.

Going back to (61), we note that all the dependence on the size and shape of the hole is captured by the third determinant, which we now proceed to study. To keep the discussion simple we take the hole to be a long slit of width \( W \) and length \( L = L_3 \). We expand the field in the slit in modes analogous to (28) and (29),

\[
\psi_{\omega kn} = \sqrt{\frac{2}{W}} \sin(n \pi x/W). \tag{65}
\]

The slit is located at \( 0 \leq x \leq W \) so that \( n = 1, 2, 3, \ldots \)

As in Sec. III A, the operator we are interested in, namely,

\[
\mathcal{O} = P\sqrt{-\nabla^2} (1 + \coth(a\sqrt{-\nabla^2})) P
\]

can be decomposed into pole and cut contributions in this basis. The free energy \( F = \frac{i}{2\beta} \Tr \log \mathcal{O} \) can then be expanded in powers of \( \mathcal{O}^{\text{cut}} \). The matrix elements of the projected operator in (66) are given by

\[
\mathcal{O}_{mn} = \frac{4}{W} \int_0^W dx dx' \int \frac{dp}{2\pi} e^{-ip(s-x') \sin(n \pi x/W)}
\times \sin(m \pi x'/W) f(p), \tag{67}
\]

\[
f(p) = \sqrt{p^2 + \mu^2} \frac{1}{1 - \exp(-2a\sqrt{p^2 + \mu^2})}. \tag{68}
\]

To evaluate the cut terms arising from the square root factors, it is useful to write an integral representation for \( f(p) \), namely,

\[
f(p) = \frac{1}{\pi} \int_{-\infty}^{\infty} d\alpha \frac{p^2 + \mu^2}{(\alpha^2 + p^2 + \mu^2)}
\times \left[ \frac{1}{1 - \exp(2a\alpha - \epsilon)} \right].
\]

The exponent \( \epsilon \) pushes the poles at \( \alpha = n \pi/a \) to the lower half-plane. We can evaluate the \( \alpha \) integral by completing the contour in the upper half-plane; only the pole at \( \alpha = i\sqrt{p^2 + \mu^2} \) contributes and the equivalence with (67) can be easily verified. Carrying out the integration over \( x, x' \), we then find

\[
\mathcal{O}_{mn} = \frac{4}{W} \int \frac{dp}{2\pi} f(p) H(q, q'),
\]

\[
H(q, q') = \frac{1}{4} \left[ 1 + e^{i(q-q')W} - e^{i(p-q')W} - e^{-i(p-q')W} \right]
\times \left[ (p-q+ie)(p-q'-ie) \right]
\times \left[ (q+q'+q'') - (q+q'-q') \right]
\times \left[ (q+q'-q'') - (q+q'-q') \right]. \tag{69}
\]

where \( q = n \pi/W, q' = m \pi/W \). The integration over \( p \) can now be done. For a term with \( 1 + e^{i(q-q')W} - e^{i(p-q')W} \), we need to close the contour in the upper half-plane; for a term with \( e^{-i(p-q')W} \), we need to close in the lower half-plane. There will be pole contributions from the denominators \( p - q + ie \) and \( p - q' - ie \). These are identical to what we named the pole terms in \( \mathcal{O}_{mn} \). There will also be terms from the poles of \( f(p) \). The latter will correspond to the cut terms we are seeking. The evaluation of the \( p \) integral then leads to \( \mathcal{O}_{mn} = \mathcal{O}_{mn}^{\text{pole}} + \mathcal{O}_{mn}^{\text{cut}} \), with

\[
\mathcal{O}_{mn}^{\text{pole}} = \frac{2\omega(q)}{1 - e^{-2\alpha a(q)}} \delta_{mn} = 2f(q) \delta_{mn},
\]

\[
\mathcal{O}_{mn}^{\text{cut}} = \frac{4qq'}{\pi W} [1 + (-1)^{m+n}] \Delta(a, q, q'),
\]

\[
\Delta(a, q, q') = \int_0^\infty d\lambda \left[ \frac{f(\lambda)}{(q^2 - \lambda^2)^2} - \frac{f(q^2)}{(q^2 - \lambda^2)^2} \right]
\times \left[ \frac{f(q^2)}{(q^2 - \lambda^2)^2} \right], \tag{70}
\]

where \( \omega(q) = \sqrt{q^2 + \mu^2} \).

**A. The direct contribution (lowest order)**

The direct contribution to the free energy is given by

\[
\beta F = \frac{1}{2} \Tr \log \mathcal{O}^{\text{pole}} \tag{71}
\]

\[
= \frac{1}{2} \Tr \log(2\sqrt{-\nabla^2}) - \frac{1}{2} \Tr \log(1 - e^{-2a\sqrt{-\nabla^2}}), \tag{72}
\]

where \( \nabla^2_D \) is the Laplacian in the slit with Dirichlet boundary conditions at \( x = 0 \) and \( x = W \). The first term has UV
divergences but is independent of $a$. In fact it is just the lowest-order energy in a single slit which we studied in Sec. III C. There we found that the energy per unit length for a slit of width $W$ is\footnote{One can obtain this directly, as $E/L = (1/\beta L)^{1/2} \log(-\nabla^2)$, using the results in Appendix B.}

$$\frac{E}{L} = -\frac{\zeta(3)}{32\pi W^2}. \quad (73)$$

The dependence on the separation between plates is captured by the second term in (72) which is finite in the UV. Including both terms, we have the finite (renormalized) energy per unit length

$$\frac{E}{L} = -\frac{\zeta(3)}{32\pi W^2} - \frac{1}{2} \int \frac{d^2 k}{(2\pi)^2} \sum_{n=1}^{\infty} \log(1 - e^{-2\pi \sqrt{k^2 + (n\pi/W)^2}}). \quad (74)$$

This expression can be studied in various limits. As $W \rightarrow 0$ the second term makes an exponentially small correction, and we have

$$\frac{E}{L} \approx -\frac{\zeta(3)}{32\pi W^2} + \frac{1}{8aW} e^{-2\pi a/W}. \quad (75)$$

On the other hand as $W \rightarrow \infty$ the second term dominates. To study it in this limit we use the Euler-Maclaurin summation formula,

$$\sum_{n=1}^{\infty} f\left(\frac{n}{W}\right) = W \int_0^{\infty} dx f(x) - \frac{1}{2} f(0) - \sum_{m=1}^{\infty} B_{2m} \frac{f^{(2m-1)}(0)}{(2m)! W^{2m-1}}. \quad (76)$$

This leads to

$$\frac{E}{L} = \frac{\pi^2 W}{1440a^3} - \frac{\zeta(3)}{32\pi a^2} + O(1/W). \quad (77)$$

Adding this result to the bulk contribution (64), with $L_1$ and $L_3 = L$ taken to be large, we find, for the lowest order or direct contribution to the energy,

$$\frac{E^{(0)}}{L} = -\frac{\pi^2(L_1 - W)}{1440a^3} + \cdots. \quad (78)$$

The terms proportional to $1/a^2$ cancel out.\footnote{This cancellation depends on the boundary conditions at infinity used in (64), namely, Dirichlet in $x$ and periodic in $z$. With a different choice of boundary conditions at infinity the $1/a^2$ terms would not cancel.} Also the usual Casimir energy per unit area (62) in the region corresponding to the slit is canceled out and only the facing area of the two plates $L(L_1 - W)$ appears in $E^{(0)}$.

**B. First diffractive contribution (first order)**

The diffractive contribution to the 2D free energy arises from the expansion

$$-\left[\log Z - \log Z^{(0)}\right] = \frac{1}{2} \pi \log \left(\frac{\delta_{mn} - 2qq'}{\pi W} [1 + (-1)^{m+n}] \times \frac{1}{f(q')} \Delta(a, q, q')\right). \quad (79)$$

We can easily work out the higher order terms from this. In the case when $W$ is large,

$$-\log Z^{(n)} = -\frac{2}{\pi^2} \int_0^{\infty} dq q^2 \frac{1 - e^{-2\pi a\omega(q)}}{\omega(q)} \Delta(a, q, q),$$

$$\Delta(a, q, q) = \frac{1}{2q} \frac{1}{\partial q} \int_0^{\infty} d\lambda \frac{f(q) - f(q)}{\lambda^2 - q^2}. \quad (80)$$

The $n$th order term is given by

$$-\log Z^{(n)} = -L \frac{2^n}{\pi^{2n}} \int_0^{\infty} \prod_i d_q q_i^2 \frac{\Delta(a, q_1, q_2)}{f(q_1)} \frac{\Delta(a, q_2, q_3)}{f(q_2)} \cdots \frac{\Delta(a, q_n, q_1)}{f(q_n)}. \quad (81)$$

As in the case of the slit and the perpendicular plates, the renormalized expressions are obtained by subtracting the $a \rightarrow \infty$ limit.

$$-\log Z^{(n)} = -L \frac{2^n}{\pi^{2n}} \int_0^{\infty} \prod_i d_q q_i^2 \left[\frac{\Delta(a)}{f} \ast \frac{\Delta(a)}{f} \ast \cdots \ast \frac{\Delta(a)}{f}\right]. \quad (82)$$

The energy for the case of four dimensions can now be obtained by integration over $\mu$,

$$E = \int \frac{\mu \, d\mu}{2\pi} (-\log Z^{(n)}). \quad (83)$$

Evaluating the integrals numerically, we find, for the first few orders,
\[ E^{(1)} = \frac{L}{a^2}(-5.54 \times 10^{-3}) \]
\[ E^{(2)} = \frac{L}{a^2}(0.80 \times 10^{-3}) \]
\[ E^{(3)} = \frac{L}{a^2}(-0.19 \times 10^{-3}) \]
\[ E^{(4)} = \frac{L}{a^2}(0.05 \times 10^{-3}) \]
\[ E^{(5)} = \frac{L}{a^2}(-0.01 \times 10^{-3}) \]

The total value for the diffractive term, up to this order, is 
\[-4.89(2) \times 10^{-3}(L/a^2).\]  
[See the comments after (56) regarding the error estimate of the final answer.] This result is for a slit of finite, although, large width. There is no direct comparison to other methods of calculation available. However, the case of two parallel plates, one of which is semi-infinite, provides a point of comparison. The Casimir energy for this geometry has also been numerically investigated by Gies and Klingmüller [7], by the world line method of subtracting out the paths which touch both plates. Their final result for two parallel plates one of which is semi-infinite is given as

\[ E = -\frac{\pi^2 L(L_1 - W)}{1440 a^3} - \frac{\gamma L}{2 a^2} + \cdots, \quad (85) \]

where \( \gamma = 0.00523(2) \).

We have a slit of finite, although, large width. Thus there are two edges to the slit, each of length \( L \) which must be considered. If one were to remove paths from a sum-over-paths formula for the propagator, all paths which touch both edges must be removed. The calculation in [7] is for a semi-infinite plate to begin with and hence paths which touch on the edge which is far away from \( x = 0 \) are not removed. Thus our result must be divided by 2 for the edge terms to get a proper comparison. The final values for the coefficient of the \( L/a^2 \) term are in reasonably good agreement.

An exact calculation of the Casimir energy of a parabolic cylinder next to an infinite plate has been done by Graham et al. [11]. A particular limit of this gives the result for the case we are studying, namely, a semi-infinite plate next to a parallel plate. The result in [11] is \( \frac{1}{2} \gamma = 0.0025 \), again in agreement with our result and with [7].

VI. SUMMARY

We have developed a method for calculating Casimir energies, including diffractive contributions which can arise from apertures on plates and other boundary elements of the geometry. This involves the functional integration over a lower-dimensional field theory defined on such apertures. The relevant kinetic operator has an interesting structure. In the simplest cases it is of the form \( \sqrt{-\nabla^2} \), similar to what occurs in the wave functional of the field, but there are important modifications based on the geometry of the situation. In all cases, the operator acts on functions which have support only on the apertures. The matrix elements of the operator allow a clean separation of diffractive contributions from direct (or ray optics) contributions. To evaluate the relevant functional integrals we expanded in powers of the diffractive contribution. This seems to be a good approximation even though there is no explicit small parameter in the problem.

In this paper we focused on the Casimir energy for some special cases: a single slit, two parallel plates, one of which has a long slit in it, and two perpendicular plates separated by a gap. In the latter two cases numerical calculations based on world line methods have been performed. Our results can be compared, and in both cases the agreement is quite good. But the method we have developed is quite general and can be applied to a variety of different geometries. For instance it can be easily generalized to arbitrary dimensions. In fact working in \( d \) dimensions might justify the perturbation series, as an expansion in powers of \( 1/d \).

The method could also be extended to include finite temperature effects, which would allow a comparison with the results of [12].

ACKNOWLEDGMENTS

We thank Rashmi Ray for collaboration at an early stage of this work. We are also grateful to Janna Levin and Alexios Polychronakos for valuable discussions. D.K. is grateful to the Aspen Center for Physics where part of this work was completed.

APPENDIX A: EXACT MODE FUNCTIONS ON AN INTERVAL AND HALF-LINE

In the formalism we have developed, effects associated with a hole are captured by nonlocal differential operators of the form \( PFP \) where \( P \) is a projection operator onto the hole and \( F \) is some function of the Laplacian on \( \mathbb{R}^{d-1} \). Diagonalizing such operators is in general difficult and we were forced to resort to perturbation theory. However one can find the exact eigenfunctions numerically. Also in some cases an analytical treatment is possible, using results obtained long ago by Malyuzhinets for scattering from a wedge [13,14]. Here we collect some of these results. Besides illustrating the nonperturbative features of the problem, our motivation is to provide evidence that a perturbative treatment should be reliable.

First consider the operator \( PFP \) where \( F = \sqrt{-d^2/dx^2} \) and \( P \) is a projection operator on the unit interval \([0,1]\). One can study this numerically, starting from a finite difference approximation to the Laplacian in position space.

\[ (F^2)_{ij} = 2, \quad (F^2)_{i,i+1} = (F^2)_{i,i-1} = -1. \quad (A1) \]

In this basis

\[ \frac{\partial}{\partial x}(PFP) = F \]
One can take the square root of (A1) numerically and diagonalize PFP. A typical eigenfunction is shown in Fig. 8. The exact eigenfunction clearly vanishes at the edges of the interval and approaches a plane wave in the middle. It is well approximated by the Dirichlet modes \sin(n \pi x) that we used as the basis for our perturbation series. Indeed the only significant difference between the exact and perturbative modes is that the exact modes go to zero more steeply at the edges of the interval.

To study this edge behavior we consider \( F = \sqrt{- (d^2/dx^2) + \mu^2} \) and take \( P \) to be a projection operator onto a half-line.

\[ P = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \]

This describes a semi-infinite “plate” embedded in two Euclidean spacetime dimensions. As this geometry has no adjustable parameters, up to renormalization the energy of such a plate vanishes, and in this sense there is nothing interesting to calculate. Instead our motivation for studying this geometry is that we will be able to diagonalize PFP analytically and show that the exact eigenfunctions have \( \sqrt{x} \) behavior as \( x \to 0 \). We will show this in two different ways: first using Laplace transforms, then by solving the wave equation following Malyuzhinets.

### 1. Laplace transform

The eigenvalue problem we wish to solve is

\[ PFP \phi(x) = \lambda \phi(x). \]  \hspace{1cm} (A3)

One way to solve (A3) is to find a function \( \phi(x) \) such that

1. \( \phi(x) \) has support for \( x > 0 \), so that \( P \phi = \phi \).
2. \( (F - \lambda)\phi \) has support for \( x < 0 \), so that \( P(F - \lambda)\phi = 0 \).

Suppose we represent \( \phi(x) \) using an inverse Laplace transform,

\[ \phi(x) = \int_{-i\infty}^{i\infty} \frac{ds}{2\pi i} e^{sx} \tilde{\phi}(s). \]  \hspace{1cm} (A4)

If \( \tilde{\phi} \) is analytic for \( \text{Re} s > 0 \), then \( \phi(x) \) will vanish for \( x < 0 \). Likewise if \( \tilde{\phi} \) is analytic for \( \text{Re} s < 0 \), then \( \phi(x) \) will vanish for \( x > 0 \). So we need to find a function \( \tilde{\phi}(s) \) such that

1. \( \tilde{\phi}(s) \) is analytic for \( \text{Re} s > 0 \).
2. \( (\sqrt{\mu^2 - s^2} - \lambda)\tilde{\phi}(s) \) is analytic for \( \text{Re} s < 0 \).

It is convenient to work on the covering space of the cut s plane, making a change of variables \( s = i \mu \sinh z \). We also set \( \lambda = \mu \cosh \xi \).\(^{10}\) Then (A4) becomes

\[ \phi(x) = \frac{\mu}{2\pi} \int_{-\infty}^{\infty} dz \cosh z e^{i\mu x \sinh z} \tilde{\phi}(z). \]

If \( \tilde{\phi}(z) \) is analytic in the strip \( -\pi \leq \text{Im} z \leq 0 \) and satisfies

\[ \tilde{\phi}(z) = \tilde{\phi}(-z - i\pi), \]

then we can replace

\[ \int_{-\infty}^{\infty} dz \to \frac{1}{2} \left( \int_{-\infty}^{0} + \int_{0}^{\infty - i\pi} + \int_{\infty - i\pi}^{0} + \int_{0}^{\infty - i\pi} \right) dz \]

and \( \phi(x) \) will vanish for \( x < 0 \). [The conditions on \( \phi(z) \) correspond to the requirement that \( \tilde{\phi}(s) \) is analytic and single valued for \( \text{Re} s \geq 0 \).] Likewise if \( \tilde{\phi}(z) \) is analytic in the strip \( 0 \leq \text{Im} z \leq \pi \) and satisfies

\[ \tilde{\phi}(z) = \tilde{\phi}(-z + i\pi) \]

[corresponding to the requirement that \( \tilde{\phi}(s) \) is analytic and single valued for \( \text{Re} s < 0 \) then \( \phi(x) \) will vanish for \( x > 0 \). So corresponding to the conditions on \( \tilde{\phi}(s) \), we need a function \( \tilde{\phi}(z) \) such that

1. \( \tilde{\phi}(z) \) is analytic for \( -\pi \leq \text{Im} z \leq 0 \) and satisfies

\[ \tilde{\phi}(z) = \tilde{\phi}(-z - i\pi). \]  \hspace{1cm} (A5)

2. \( (\cosh z - \cosh \xi)\tilde{\phi}(z) \) is analytic for \( 0 \leq \text{Im} z \leq \pi \) and satisfies

\[ (\cosh z - \cosh \xi)\tilde{\phi}(z) = -(\cosh z + \cosh \xi) \times \tilde{\phi}(-z + i\pi). \]  \hspace{1cm} (A6)

A solution to this system of equations was obtained by Malyuzhinets [13, 14]. Define

\(^{10}\)The \( \delta \)-function normalizable spectrum of PFP is \( \lambda \in [\mu, \infty) \) corresponding to \( 0 \leq \xi < \infty \).
Then the solution is
\[
\Psi_\pi(z) = \psi_a\left(-iz + \frac{3\pi}{2} + i\xi\right)\psi_a\left(-iz - \frac{3\pi}{2} - i\xi\right)
\times \psi_a\left(-iz - \frac{\pi}{2} + i\xi\right)\psi_a\left(-iz - \frac{\pi}{2} - i\xi\right).
\]

where
\[
\psi_a(z) = \exp\left(-\frac{1}{2} \int_0^\infty dt \frac{\cosh(tz) - 1}{t \cosh(t\pi/2) \sinh(2\alpha t)}\right).
\]

Then the solution is
\[
\tilde{\phi}(z) = \frac{1}{(\sinh z - i\epsilon)^2 - \sinh^2 \xi} \Psi_\pi(z).
\] (A7)

To see this, note that \(\Psi_\pi(z)\) was constructed to satisfy (A5) and (A6) all by itself. Moreover the prefactor \(1/(\sinh^2 z - \sinh^2 \xi)\) is invariant under \(z \rightarrow -z \pm i\pi\), so \(\tilde{\phi}(z)\) also satisfies (A5) and (A6). It only remains to check the analyticity conditions. In the strip \(-\pi \leq \text{Im} z \leq \pi\) one can show that \(\Psi_\pi(z)\) has no poles. It does, however, have zeros at \(z = \pm \xi + i\pi\). In the same strip the prefactor has poles at \(z = \pm \xi + i\epsilon\) and \(z = \pm \xi + i\pi - i\epsilon\), but the latter poles cancel against the zeros of \(\Psi_\pi\). So in the strip \(\tilde{\phi}\) has poles at \(z = \pm \xi + i\epsilon\). That is, \(\tilde{\phi}(z)\) is analytic for \(-\pi \leq \text{Im} z \leq 0\) and, when multiplied by \(\cosh z - \cosh \xi\), it becomes analytic for \(0 \leq \text{Im} z \leq \pi\).

One comment on this solution is in order. Up to a normalization the prefactor in (A7) is the Laplace transform of \(\theta(x) \sin kx\), where \(k = M \sin \xi\) exactly the modes with Dirichlet boundary conditions that were the starting point for our perturbation theory. So in the case of a semi-infinite plate, diffractive corrections to the perturbative modes are given by the Malyuzhinets function \(\Psi_\pi(z)\).

### 2. Wave equation in a wedge

Another approach to diagonalizing PFP more closely makes contact with the original work of Malyuzhinets. Consider a semi-infinite plate in two Euclidean dimensions, and let us study the wave functional for the field on a “hole” which is a half-line making an angle \(\alpha\) with respect to the plate. The geometry is shown in Fig. 9. In general the surface actions appearing in (8) and (9) can be written as

\[
S = \int \text{hole} \, \frac{1}{2} \phi_{cl} n \cdot \partial \phi_{cl},
\]

where \(\phi_{cl}\) is a solution to \((-\Box + \nu^2)\phi_{cl} = 0\) with the boundary conditions \(\phi_{cl} = 0\) at \(\theta = 0\), \(\phi_{cl} = \phi_0\) at \(\theta = \alpha\). Rather than specify the value of \(\phi_0\), suppose we impose \(n \cdot \partial \phi_{cl} = \lambda \phi_{cl}\) at \(\theta = \alpha\). That is, suppose we solve the system

\[
(-\Box + \nu^2) \phi_{cl} = 0, \quad \phi_{cl} = 0, \quad n \cdot \partial \phi_{cl} = \lambda \phi_{cl},
\]

where
\[
\phi_{cl}(r, \theta) = \int_{\gamma_+ \cup \gamma^-} \frac{dz}{2\pi i} e^{-\nu r \cos(\theta - \gamma)} f(z) g(z),
\]

where
\[
f(z) = \psi_a(z + \alpha + i\xi)\psi_a(z + \alpha - i\xi)\psi_a(z - \alpha + i\xi)
\times \psi_a(z - \alpha - i\xi)
\]

is the function introduced by Malyuzhinets and
\[
g(z) = \frac{1}{\sin^2(\nu z) - \sin^2(\nu \beta)}
\]

is chosen to obtain the correct asymptotic behavior at large \(r\). Here \(\nu = \pi/2\alpha\) and \(\beta = \pi/2 - \alpha + i\xi\). The contour \(\gamma_+\) starts at \(z = 2\pi + i\infty\), descends toward the real axis, moves to \(2\pi\) to the left while staying above any singularities of the integrand, and returns to \(+i\infty\), while \(\gamma_-\) is the mirror image of \(\gamma_+\) under \(z \rightarrow -z\).

One can extract the asymptotic behavior of the solution from the contour integral representation [13,14]. Along the Robin boundary \(\phi_{cl}\) has plane-wave behavior at large \(r\), while near the origin it has power-law behavior \(\phi_{cl}(r) \sim r^{\pi/2\alpha}\). Setting \(\alpha = \pi\), this means eigenfunctions

![Diagram](image-url)
of $PFP$ have plane-wave behavior far from the edge, while near the edge they vanish like $\sqrt{r}$ as $r \to 0$.

**APPENDIX B: HEAT KERNELS**

For a free scalar field of mass $m$ in Euclidean space, with some number of periodic dimensions and some number of Dirichlet directions, the partition function is

$$Z = e^{-\beta F} = \det^{-1/2}(-\Box + m^2).$$

Here $\beta$ is just the periodicity around some “Euclidean time” direction. We can represent

$$x_i \text{ periodic with period } L_i \Rightarrow \text{eigenvalues} - \left(\frac{2\pi n}{L_i}\right)^2, \quad n \in \mathbb{Z},$$

$$x_i \text{ Dirichlet with size } L_i \Rightarrow \text{eigenvalues} - \left(\frac{\pi n}{L_i}\right)^2, \quad n \in \mathbb{N}.$$

This means that the heat kernel factorizes, $K(s) = \prod_i K_i$, where

$$x_i \text{ periodic } \Rightarrow K_i = K_p(s, L_i) = \sum_{n \in \mathbb{Z}} e^{-s(2\pi n/L_i)^2},$$

$$x_i \text{ Dirichlet } \Rightarrow K_i = K_d(s, L_i) = \sum_{n \in \mathbb{N}} e^{-s(\pi n/L_i)^2}.$$  

Note that

$$K_d(s, L) = \frac{1}{2}(K_p(s, 2L) - 1). \quad (B2)$$

By Poisson resummation

$$K_p(s, L) = \frac{L}{\sqrt{4\pi s}} \sum_{n \in \mathbb{Z}} e^{-L^2 n^2/4s} = \theta_3\left(0, \frac{i4\pi s}{L^2}\right). \quad (B3)$$

The expressions (B2) and (B3) make it clear that as $s \to 0$ we have

$$K(s) \sim K_0(s) = \prod_p \frac{L_p}{\sqrt{4\pi s}} \prod_{D} \left(\frac{L_D}{\sqrt{4\pi s}} - \frac{1}{2}\right).$$

This isolates the UV divergence: when we use this small-$s$ behavior in the integral (B1) we get a divergence as $\epsilon \to 0$.

$$\beta F = \frac{1}{2} \text{Tr} \log(-\Box + m^2) = -\frac{1}{2} \int_0^\infty \frac{ds}{s} e^{-(s(-\Box + m^2))}, \quad (B1)$$

where $\epsilon \to 0$ serves as a UV regulator. To compute the (trace of the) heat kernel

$$K(s) = \text{Tr} e^{s\Box},$$

we use the fact that $\Box = \sum \frac{\partial^2}{\partial x_i^2}$ where the eigenvalues of $\partial_i^2$ are

$$\text{eigenvalues} - \left(\frac{2\pi n}{L}\right)^2, \quad n \in \mathbb{Z},$$

$$\text{eigenvalues} - \left(\frac{\pi n}{L}\right)^2, \quad n \in \mathbb{N}.$$  

To get a finite answer we just subtract off the contribution of $K_0$. This has the interpretation of renormalizing the various bulk and boundary cosmological constants. (Terms in $K_0$ are proportional to the total volume, or the volumes of various walls or corners.) After making the subtraction we can set $\epsilon = 0$. So the renormalized answer is

$$\beta F = -\frac{1}{2} \int_0^\infty \frac{ds}{s} e^{-sm} \left[\prod_p K_p(s, L_i) \prod_D K_d(s, L_i) - \prod_p \frac{L_i}{\sqrt{4\pi s}} \prod_D \left(\frac{L_D}{\sqrt{4\pi s}} - \frac{1}{2}\right)\right], \quad (B4)$$

where just for completeness

$$K_p(s, L) = \frac{L}{\sqrt{4\pi s}} \sum_{n \in \mathbb{Z}} e^{-L^2 n^2/4s}, \quad (B5)$$

$$K_d(s, L) = \frac{L}{\sqrt{4\pi s}} - \frac{1}{2} + \frac{L}{\sqrt{4\pi s}} \sum_{n = 1}^\infty e^{-L^2 n^2/4s}.$$
